

The candidate property behind the WM preference: humans STOP, machines CREEP — human demos fully halt 1.7x more (0.37 vs 0.22 of decisions, $d=+1.16$); at a loose 2 mm threshold the arms are indistinguishable (50% vs 48%) — the signal is true rest states + stop-to-start transients, not slowness

(a) strongest same-trial contrast (uid 305) (b) every tape: speed over time (black = FULL STOP <0.5mm) (c) full-stop fraction per tape ($d=+1.16$)
